Value-at-Risk

- Easy to understand
- Historically the most used risk-measure
- Undesirable computational properties
- Does not differentiate between large and catastrophic losses

$$VaR_{\alpha}(Z) = F^{-1}(\alpha) = \max\{z|F(z) \le \alpha\}$$

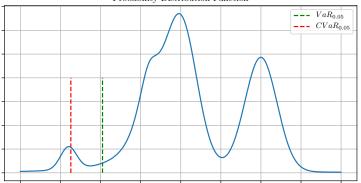

Conditional Value-at-Risk

- Coherent risk measure
- ullet Basel Committee on Banking Supervision o CVaR
- Equivalent to robustness

$$\mathsf{CVaR}_{\alpha}(Z) = \frac{1}{\alpha} \int_0^{\alpha} F_Z^{-1}(\beta) \mathsf{d}\beta = \frac{1}{\alpha} \int_0^{\alpha} \mathsf{VaR}_{\beta}(Z) \mathsf{d}\beta$$

VaR, CVaR

Reinforcement Learning

Definition

An MDP is a 5-tuple $\mathcal{M} = (\mathcal{X}, \mathcal{A}, R, P, \gamma)$, where \mathcal{X} and \mathcal{A} are the finite state and action spaces.

 $R(x,a) \in [R_{\min}, R_{\max}]$ is a random variable representing the reward generated by being in state x and selecting action a; $P(\cdot|x,a)$ is the transition probability distribution; $\gamma \in [0,1)$ is a discount factor. We also assume we are given a starting state x_0 .

Goal

Definition

 $Z^{\pi}(x_t)$ Is a random variable representing the discounted reward along a trajectory generated by the MDP by following the policy π , starting at state x_t .

$$Z^{\pi}(x_t) = \sum_{t=0}^{\infty} \gamma^t R(x_t, \pi(x_t))$$

Reinforcement Learning with CVaR

For a given α , our goal is to find a globally optimal policy π^*

$$\pi^* = \arg\max_{\pi} \mathit{CVaR}^\pi_{\alpha}(\mathit{Z}^\pi(x_0))$$

Value Iteration

Theorem (CVaR decomposition)

For any $t \ge 0$, denote by $Z = (Z_{t+1}, Z_{t+2}, ...)$ the reward sequence from time t+1 onwards. The conditional CVaR under policy π obeys the following decomposition:

$$\mathit{CVaR}_{\alpha}\left(\mathit{Z}^{\pi}(x, \mathit{a})\right) = \min_{\xi \in \mathcal{U}_{\mathit{CVaR}}(\alpha, P(\cdot | x, \mathit{a}))} \sum_{x'} \mathit{p}(x' | x, \mathit{a}) \xi(x') \mathit{CVaR}_{\xi(x')\alpha}\left(\mathit{Z}^{\pi}(x')\right)$$

Theorem (CVaR Value Iteration)

The following Bellman operator is a contraction:

$$\mathbf{T}V(x,y) = \max_{a} \left[R(x,a) + \gamma \min_{\xi} \sum_{x'} p(x'|x,a)\xi(x')V\left(x',y\xi(x')\right) \right]$$

40 > 40 > 42 > 42 > 2 90

CVaR Value Iteration

Theorem (CVaR Value Iteration)

The following Bellman operator is a contraction:

$$\mathbf{T}V(x,y) = \max_{a} \left[R(x,a) + \gamma \min_{\xi} \sum_{x'} p(x'|x,a) \xi(x') V\left(x',y\xi(x')\right) \right]$$

The operator **T** describes the following relationship:

$$TCVaR_y(Z(x)) = \max_{a} [R(x, a) + \gamma CVaR_y(Z(x, a))]$$

Linear interpolation

Computing operator T s intractable, as the state-space is continuous. A solution would be to approximate the operator with linear interpolation.

Theorem

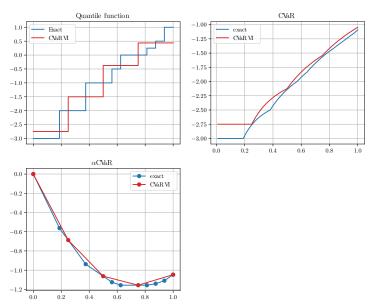

The function $\alpha CVaR_{\alpha}$ is convex. The operator $T_{\mathcal{I}}$ is a contraction.

$$\mathcal{I}_{x}[V](y) = y_{i}V(x, y_{i}) + \frac{y_{i+1}V(x, y_{i+1}) - y_{i}V(x, y_{i})}{y_{i+1} - y_{i}}(y - y_{i})$$

$$\mathbf{T}_{\mathcal{I}}V(x,y) = \max_{a} \left[R(x,a) + \gamma \min_{\xi} \sum_{x'} p(x'|x,a) \frac{\mathcal{I}_{x'}[V](y\xi(x'))}{y} \right]$$

This iteration can be formulated and solved as a linear program.

$\alpha \text{CVaR}_{\alpha}$ duality

Lemma

Any discrete distribution has a piecewise linear $\alpha CVaR_{\alpha}$ function. Similarly, any a piecewise linear $\alpha CVaR_{\alpha}$ function can be seen as representing a certain discrete distribution.

$$\alpha\mathsf{CVaR}_\alpha \Leftarrow \mathsf{VaR}$$

$$\frac{\partial}{\partial \alpha} \alpha \mathsf{CVaR}_{\alpha}(Z) = \frac{\partial}{\partial \alpha} \int_{0}^{\alpha} \mathit{VaR}_{\beta}(Z) d\beta = \mathit{VaR}_{\alpha}(Z)$$

$$\alpha \mathsf{CVaR}_{\alpha} \Rightarrow \mathsf{VaR}$$

$$\alpha \mathsf{CVaR}_{\alpha}(Z) = \int_{0}^{\alpha} \mathit{VaR}_{\beta}(Z) \mathsf{d}\beta$$

Linear-time Computation

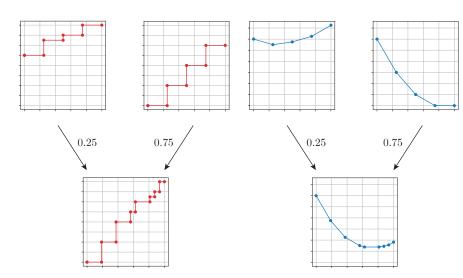

Theorem

Solution to minimization problem present in the CVaR Value Iteration can be computed by setting

$$\xi(x') = \frac{F_{x'}(F_x^{-1}(\alpha))}{\alpha}$$

The computational complexity is $O(n \cdot m)$ where n is the number of transition states and m is the number of atoms.

Next state CVaR computation

VaR-based Policy Improvement

Theorem

Let π be a fixed policy, $\alpha \in (0,1]$. By following policy π' from the following algorithm, we will improve $CVaR_{\alpha}(Z)$ in expectation:

$$CVaR_{lpha}(Z^{\pi}) \leq CVaR_{lpha}(Z^{\pi'})$$

input
$$\alpha, x_0, \gamma$$

 $a = \arg\max_a CVaR_{\alpha}(Z(x_0, a))$
 $s = VaR_{\alpha}(Z(x_0, a))$
 $x_t, r_t = \operatorname{envTransition}(x_0, a)$
while x_t is not terminal do
 $s = \frac{s - r_t}{\gamma}$
 $a = \arg\max_a \mathbb{E}\left[(Z(x_t, a) - s)^-\right]$
 $x_t, r_t = \operatorname{envTransition}(x_t, a)$
end while
